Terraform: AWS Three-Tier Architecture Design

In this project, we will create a three-tier architecture leveraging Terraform modules to make the process easily repeatable and reusable. Our architecture will reside in a

custom VPC.

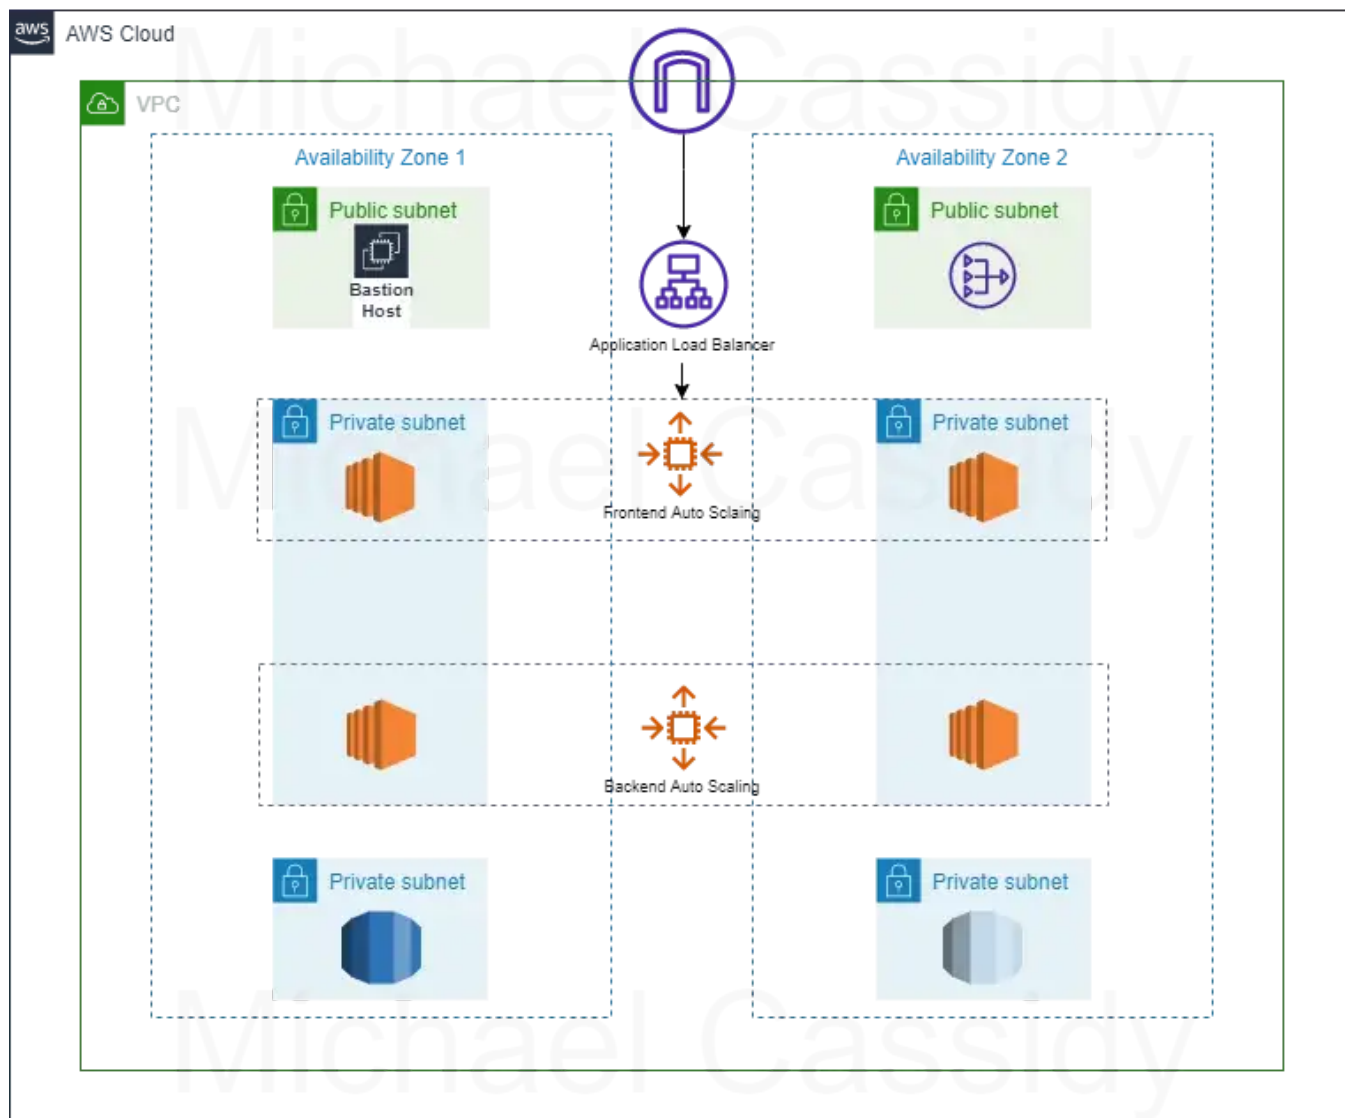

The web tier will have a bastion host and NAT gateway in the public subnets. The bastion host will serve as our access point to the underlying infrastructure. The NAT Gateway will allow our private subnets to access updates from the internet.

In the application tier, we will create an internet facing load balancer to direct internet traffic to an autoscaling group in the private subnets, along with a backend autoscaling group for our backend application. We will create a script to install the apache webserver in the frontend, and a script to install Node.js in the backend.

We will have another layer of private subnets in the database tier hosting a MySQL database which will eventually access using Node.js. Keep in mind, this is simply an example of infrastructure one could use for a web application.

I will be using Visual Studio Code as my IDE, but feel free to use Cloud9 or another IDE of your choice. The steps in this tutorial will differ slightly if you choose to use a different IDE.

Here's a close up of our architecture:

Prerequisites

- AWS Account
- Proper Permissions for your user
- Terraform installed on your IDE
- AWS CLI installed and configured on your IDE
- SSH Agent (For Windows PowerShell)

Set Up

I will briefly go over the filesystem I will be using for this project. To learn more about why I use it for Terraform modules, and specifically AWS infrastructure,

please check out my article on Reusable EC2 Instances:

<https://betterprogramming.pub/reusable-ec2-instances-using-terraform-modules-59aac51f1fb>

Filesystem

In this filesystem, I have created folders that will represent the root (*terraform*), development environment (*dev*), in the *us-east-1* region, and utilizing the *t2.micro* instance type. The final folder will be the folder where all the root files reside. The next set of folders will represent the modules (*modules*). The modules folder consists of the 4 modules (*compute*, *database*, *loadbalancing*, *network*).

CODE

Let's start out in the root *main.tf* file. Here we will set up the locals block to refer to the folder system. We will also reference each module that we will be working with. Within each module block, different variables are defined. These variables are each introduced in the *variables.tf* files for each module. In the *main.tf* files of each module, we will point to these specified variables.

```
1  # --- root/main.tf ---
2
3  provider "aws" {
4      region = local.location
5  }
6
7  locals {
8      cwd          = reverse(split("/", path.cwd))
9      instance_type = local.cwd[1]
10     location      = local.cwd[2]
11     environment    = local.cwd[3]
12     vpc_cidr       = "10.123.0.0/16"
13 }
14
15 module "networking" {
16     source          = "../../../../../modules/three-tier-deployment/networking"
17     vpc_cidr        = local.vpc_cidr
18     access_ip       = var.access_ip
19     public_sn_count = 2
20     private_sn_count = 2
21     db_subnet_group = true
22     availabilityzone = "us-east-1a"
23     azs             = 2
24 }
25
26 module "compute" {
27     source          = "../../../../../modules/three-tier-deployment/compute"
28     frontend_app_sg = module.networking.frontend_app_sg
29     backend_app_sg  = module.networking.backend_app_sg
30     bastion_sg      = module.networking.bastion_sg
31     public_subnets = module.networking.public_subnets
32     private_subnets = module.networking.private_subnets
33     bastion_instance_count = 1
34     instance_type     = local.instance_type
35     key_name           = "Three-Tier-Terraform"
36     lb_tg_name        = module.loadbalancing.lb_tg_name
37     lb_tg             = module.loadbalancing.lb_tg
38
39 }
40
41 module "database" {
42     source          = "../../../../../modules/three-tier-deployment/database"
43     db_storage      = 10
44     db_engine_version = "5.7.22"
45     db_instance_class = "db.t2.micro"
46     db_name         = var.db_name
47     dbuser          = var.dbuser
48     dbpassword       = var.dbpassword
```

```
48     db_password      = var.db_password
49     db_identifier     = "three-tier-db"
50     skip_db_snapshot = true
51     rds_sg            = module.networking.rds_sg
52     db_subnet_group_name = module.networking.db_subnet_group_name[0]
53 }
54
55 module "loadbalancing" {
56     source = "../../../../../modules/three-tier-
deployment/loadbalancing"
57     lb_sg      = module.networking.lb_sg
58     public_subnets = module.networking.public_subnets
59     tg_port    = 80
60     tg_protocol = "HTTP"
61     vpc_id     = module.networking.vpc_id
62     app_asg    = module.compute.app_asg
63     listener_port = 80
64     listener_protocol = "HTTP"
65     azs        = 2
66 }
```

networking-vpc-ig-main.tf hosted with ❤️ by GitHub

[view raw](#)

Next up we will create the public subnets using a count variable to control the number we want. We will set up the `cidr_block` so that the subnets can exist within the specified VPC cidr range. The public subnet route table will route to the internet gateway. We will also create the NAT gateway that will connect with our private instances.

```
1  ### PUBLIC SUBNETS (WEB TIER) AND ASSOCIATED ROUTE TABLES
2
3  resource "aws_subnet" "three_tier_public_subnets" {
4      count                        = var.public_sn_count
5      vpc_id                     = aws_vpc.three_tier_vpc.id
6      cidr_block                 = "10.123.${10 + count.index}.0/24"
7      map_public_ip_on_launch    = true
8      availability_zone          = data.aws_availability_zones.available.names[count.index]
9
10     tags = {
11         Name = "three_tier_public_${count.index + 1}"
12     }
13 }
14
15 resource "aws_route_table" "three_tier_public_rt" {
16     vpc_id = aws_vpc.three_tier_vpc.id
17
18     tags = {
19         Name = "three_tier_public"
20     }
21 }
22
23 resource "aws_route" "default_public_route" {
24     route_table_id      = aws_route_table.three_tier_public_rt.id
25     destination_cidr_block = "0.0.0.0/0"
26     gateway_id          = aws_internet_gateway.three_tier_internet_gateway.id
27 }
28
29 resource "aws_route_table_association" "three_tier_public_assoc" {
30     count                = var.public_sn_count
31     subnet_id           = aws_subnet.three_tier_public_subnets.*.id[count.index]
32     route_table_id      = aws_route_table.three_tier_public_rt.id
33 }
34
35
36 ### EIP AND NAT GATEWAY
37
38 resource "aws_eip" "three_tier_nat_eip" {
39     vpc = true
40 }
41
42 resource "aws_nat_gateway" "three_tier_ngw" {
43     allocation_id      = aws_eip.three_tier_nat_eip.id
44     subnet_id          = aws_subnet.three_tier_public_subnets[1].id
45 }
```

We will create the private subnets next that will reside in the application tier and database tier. Here will will associate a private route table with the NAT Gateway.

Open in app ↗

Get unlimited access

```

1  ### PRIVATE SUBNETS (APP TIER & DATABASE TIER) AND ASSOCIATED ROUTE TABLES

networking-private-subnet-main.tf hosted with ❤ by GitHub [view raw](#)

for the last part of the *main.tf* networking file, we will make security groups (sg) to allow proper permissions for each level. The bastion sg will allow you to connect to the bastion EC2 instance. Ideally, you would set the *access_ip* variable to your IP address. I have set it to allow any IP address, but that is not most secure. We have the load balancer sg, frontend app sg, backend app sg, and database sg. The description in each block tells us their purpose. I have also thrown in a database subnet group so that we can add it to our database subnets we created earlier.

```
1  ### SECURITY GROUPS
2
3  resource "aws_security_group" "three_tier_bastion_sg" {
4      name          = "three_tier_bastion_sg"
5      description   = "Allow SSH Inbound Traffic From Set IP"
6      vpc_id        = aws_vpc.three_tier_vpc.id
7
8      ingress {
9          from_port = 22
10         to_port   = 22
11         protocol  = "tcp"
12         cidr_blocks = [var.access_ip]
13     }
14
15     egress {

45 }
```

Compute

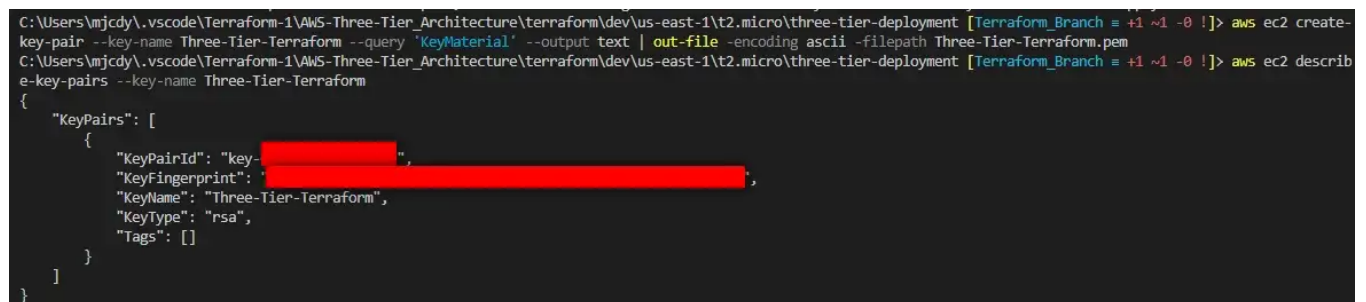

We will now head over to the compute module. For our *main.tf* file, we will obtain the latest AMI using the AWS SSM parameter store. Next, to be able to access our Bastion host, we will need a key pair. Let's generate one from the CLI. Enter the following command. Replace the *italicized* characters with your own:

```
aws ec2 create-key-pair --key-name MyKeyPair --query 'KeyMaterial' -  
-output text | out-file -encoding ascii -filepath MyKeyPair.pem
```

To display the keypair you created, enter the following command:

```
aws ec2 describe-key-pairs --key-name MyKeyPair
```

Your AWS account will hold the keypair. Here is what the process looks like from my command line:

```
C:\Users\mjcdy\.vscode\Terraform-1\AWS-Three-Tier_Architecture\terraform\dev\us-east-1\t2.micro\three-tier-deployment [Terraform_Branch = +1 ~1 -0 !]> aws ec2 create-  
key-pair --key-name Three-Tier-Terraform --query 'KeyMaterial' --output text | out-file -encoding ascii -filepath Three-Tier-Terraform.pem  
C:\Users\mjcdy\.vscode\Terraform-1\AWS-Three-Tier_Architecture\terraform\dev\us-east-1\t2.micro\three-tier-deployment [Terraform_Branch = +1 ~1 -0 !]> aws ec2 describ  
e-key-pairs --key-name Three-Tier-Terraform  
{  
  "KeyPairs": [  
    {  
      "KeyPairId": "key- [REDACTED]",  
      "KeyFingerprint": "[REDACTED]",  
      "KeyName": "Three-Tier-Terraform",  
      "KeyType": "rsa",  
      "Tags": []  
    }  
  ]  
}
```

For Windows

I use X Certificate and Key Manager to store my *keypair.pem* files. Make sure to locate the PEM file you made in your Windows filesystem. Create a keypair folder and move the PEM file to that location. Copy the path in your Windows file system by right clicking on the keypair PEM file:

We will come back to the keypair later.

Now we will create our auto scaling groups in the private subnets. We will attach our scripts to the appropriate group. The bastion auto scaling group could be set as a single instance, but we will create an autoscaling group because a failed host will be replaced automatically if EC2 health checks are failed. Finally we will attach the frontend group to the internet facing load balancer.

```

Below are the *variables.tf* and *outputs.tf* files for the loadbalancing module:

Database

Onto the last module. For the *main.tf* file here, we have a block that builds the database. One thing you could add for additional security is a KMS key to encrypt the database.

Below are the *variables.tf* and *outputs.tf* files for the database:

Finally, back at the root folder, we will add the *variables.tf* file, *outputs.tf* file, and the *tfvars* file:

The *outputs.tf* root file will tell Terraform to output the code values in our terminal. We will return the endpoints for our load balancer and database:

Here are the scripts I used to install Apache and Node.js. The Apache script will allow you to test the internet facing load balancer:

Terraform Commands

Now that the infrastructure as code is set up, we can apply it to our AWS account. From the root directory, run a `terraform init`, then `terraform validate` if you want to see the validity of your code, `terraform plan` to map out the resources you will create, and `terraform apply` to execute the plan!

After your plan, you will see the number of resources to be created, and the outputs you will be shown. After the apply is complete, you should see that all of your resources have been created, along with the load balancer endpoints.

```
Apply complete! Resources: 37 added, 0 changed, 0 destroyed.
```

Outputs:

```
database_endpoint = "three-tier-db.clmzzmv9z7zf.us-east-1.rds.amazonaws.com:3306"  
load_balancer_endpoint = "three-tier-loadbalancer-1977327318.us-east-1.elb.amazonaws.com"
```

Testing

If you go into your AWS console, you should be able to see the VPC and subnets, internet gateway, route tables and associations, EC2 instances running in the proper locations, load balancers, and RDS database.

Database

three-tier-db

Summary			
DB identifier three-tier-db	CPU 3.00%	Status Available	Class db.t2.micro
Role Instance	Current activity 0 Connections	Engine MySQL Community	Region & AZ us-east-1a

Connectivity & security | Monitoring | Logs & events | Configuration | Maintenance & backups | Tags

Connectivity & security

Endpoint & port	Networking	Security
Endpoint three-tier-db.clmzzmv9z7zf.us-east-1.rds.amazonaws.com	Availability Zone us-east-1a	VPC security groups three-tier_rds_sg (sg-0a601c6bd264b0703) Active
Port 3306	VPC three_tier_vpc-100 (vpc-068b9ca43e5eeeb20)	Public accessibility No

If we copy the load balancer endpoint we got from our Terraform output, and place it in the search bar, we will see the message we specified in our script for the Apache webserver.

Hello World from ip-10-123-21-240.ec2.internal

If we refresh the page, we should see the IP address from the other instance in our frontend autoscaling group.

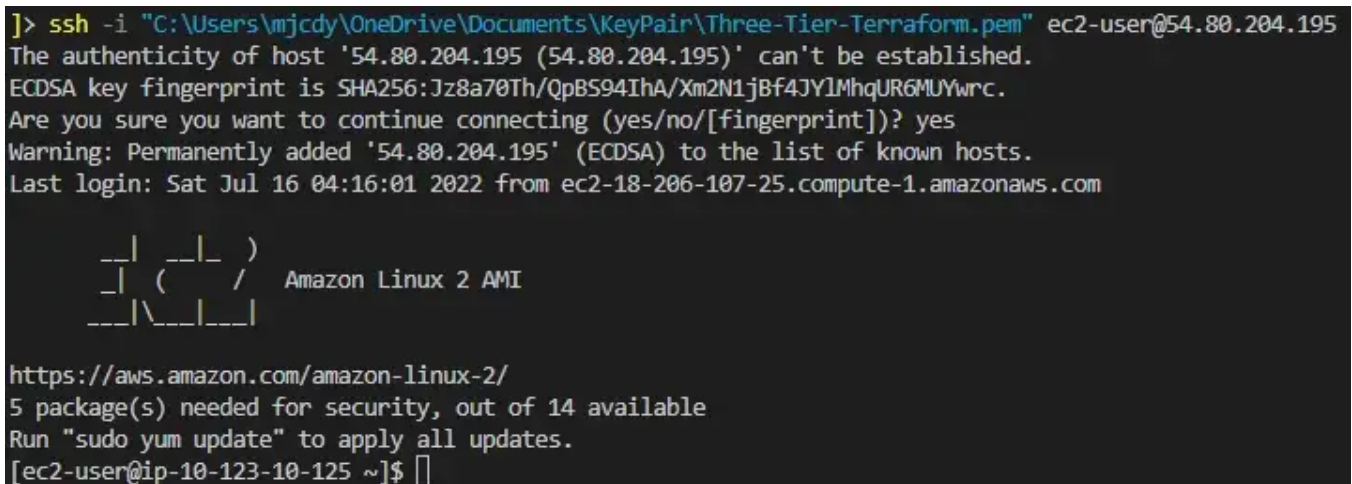

Hello World from ip-10-123-20-80.ec2.internal

Make sure to test out the infrastructure. You will need to use the keypair to SSH into the bastion host. Locate the public IP address of your Bastion Instance in the console:

```
ssh -i <Keypair_Path> ec2-user@<Public_IP_Address>
```

For example, my file path included looks like this:

```
ssh -i "C:\Users\mjcdy\OneDrive\Documents\KeyPair\Three-Tier-Terraform.pem" ec2-user@54.80.204.195
```

```
> ssh -i "C:\Users\mjcdy\OneDrive\Documents\KeyPair\Three-Tier-Terraform.pem" ec2-user@54.80.204.195
The authenticity of host '54.80.204.195 (54.80.204.195)' can't be established.
ECDSA key fingerprint is SHA256:Jz8a70Th/QpBS94IhA/Xm2N1jBf4JYlMhqUR6MUyWrc.
Are you sure you want to continue connecting (yes/no/[fingerprint])? yes
Warning: Permanently added '54.80.204.195' (ECDSA) to the list of known hosts.
Last login: Sat Jul 16 04:16:01 2022 from ec2-18-206-107-25.compute-1.amazonaws.com

  __|  __|_  )
 _| (  _ /   Amazon Linux 2 AMI
---| \_--|_|

https://aws.amazon.com/amazon-linux-2/
5 package(s) needed for security, out of 14 available
Run "sudo yum update" to apply all updates.
[ec2-user@ip-10-123-10-125 ~]$
```

Important

If you want to SSH into the backend application instances, you will need the SSH agent if you are using Windows PowerShell. You should be able to SSH into the frontend, then backend private subnets as well. Simply use the private IP when going into the private subnets. You will need to bring your keypair with you to each instance. Here is the command you would use to do so when entering the Bastion host:

```
ssh -A ec2-user@<Public_IP_Address>
```

This assumes your SSH agent is set up and the keypair path has been added to the agent.

```

]> ssh -A ec2-user@54.80.204.195
Last login: Sat Jul 16 04:19:25 2022 from 066-216-236-160.res.spectrum.com

  __|  __|_  )
  _| (    /   Amazon Linux 2 AMI
  ___|\___|___|

https://aws.amazon.com/amazon-linux-2/
5 package(s) needed for security, out of 14 available
Run "sudo yum update" to apply all updates.
[ec2-user@ip-10-123-10-125 ~]$

```

Now that we are in the Bastion Host instance, let's move onto the frontend application instances where the Apache webserver is installed:

```

[ec2-user@ip-10-123-10-125 ~]$ ssh ec2-user@10.123.20.122
The authenticity of host '10.123.20.122 (10.123.20.122)' can't be established.
ECDSA key fingerprint is SHA256:DxKFi3g2gcnaQtNzpcHw+5uH+sYsFCUk5auz+9E3piM.
ECDSA key fingerprint is MD5:07:ef:c4:06:ea:14:4a:75:12:a2:12:43:af:de:5b:9c.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added '10.123.20.122' (ECDSA) to the list of known hosts.

  __|  __|_  )
  _| (    /   Amazon Linux 2 AMI
  ___|\___|___|

https://aws.amazon.com/amazon-linux-2/
[ec2-user@ip-10-123-20-122 ~]$ exit
logout
Connection to 10.123.20.122 closed.
[ec2-user@ip-10-123-10-125 ~]$ ssh -A ec2-user@10.123.20.122
Last login: Sat Jul 16 04:38:01 2022 from ip-10-123-10-125.ec2.internal

  __|  __|_  )
  _| (    /   Amazon Linux 2 AMI
  ___|\___|___|

https://aws.amazon.com/amazon-linux-2/
[ec2-user@ip-10-123-20-122 ~]$

```

As you can see, I forgot to bring the keys with me, so I had to go back to the Bastion host to get them!

I will switch over to the other frontend instance in my autoscaling group and check to see if Apache is installed:

```

[ec2-user@ip-10-123-21-126 ~]$ httpd -v
Server version: Apache/2.4.54 ()
Server built:   Jun 30 2022 11:02:23
[ec2-user@ip-10-123-21-126 ~]$

```

In order to get into one of the backend application instances, we will go back to the Bastion, and then go to the backend:

```
[ec2-user@ip-10-123-21-126 ~]$ exit
logout
Connection to 10.123.21.126 closed.
[ec2-user@ip-10-123-10-125 ~]$ ssh -A ec2-user@10.123.21.191
The authenticity of host '10.123.21.191 (10.123.21.191)' can't be established.
ECDSA key fingerprint is SHA256:SFnP05ZpEhR5I7ApPeByC750G+4vIWmf9fqvs1NUuz0.
ECDSA key fingerprint is MD5:df:9a:c3:b0:99:7b:71:bf:cc:62:a9:89:5b:58:63:30.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added '10.123.21.191' (ECDSA) to the list of known hosts.

  __|  __|_ )
  _| (    /   Amazon Linux 2 AMI
 ___|\___|___|

https://aws.amazon.com/amazon-linux-2/
4 package(s) needed for security, out of 7 available
Run "sudo yum update" to apply all updates.
[ec2-user@ip-10-123-21-191 ~]$
```

Now we can check to see if Node.js was installed:

```
Run "sudo yum update" to apply all updates.
[ec2-user@ip-10-123-21-191 ~]$ node --version
v16.16.0
[ec2-user@ip-10-123-21-191 ~]$
```

Now we will install the MySQL driver to access our AWS database using Node.js. Use the command `npm install mysql`. Then we will make a JavaScript file to connect with the database:

```
[ec2-user@ip-10-123-21-191 ~]$ npm install mysql

added 11 packages, and audited 12 packages in 978ms

npm notice
npm notice New minor version of npm available! 8.11.0 -> 8.14.0
npm notice Changelog: https://github.com/npm/cli/releases/tag/v8.14.0
npm notice Run npm install -g npm@8.14.0 to update!
npm notice
[ec2-user@ip-10-123-21-191 ~]$ touch mysql_connection.js
[ec2-user@ip-10-123-21-191 ~]$ ls
mysql_connection.js  node_modules  package.json  package-lock.json
[ec2-user@ip-10-123-21-191 ~]$ vim
[ec2-user@ip-10-123-21-191 ~]$ vim mysql_connection.js
```

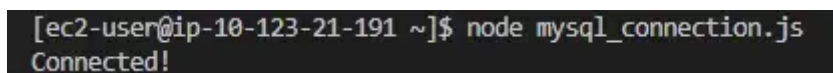

Go in to edit the file using vim, or your preferred text editor:

```
var mysql = require('mysql');  
var con = mysql.createConnection({  
  host: "database_endpoint from Terraform Output",  
  user: "dbuser from tfvars file",  
  password: "dbpassword from tfvars file"  
});  
con.connect(function(err) {  
  if (err) throw err;  
  console.log("Connected!");  
});
```

```
var con = mysql.createConnection({  
  host: "three-tier-db.clmzzmv9z7zf.us-east-1.rds.amazonaws.com",  
  user: "admin",  
  password: "[REDACTED]"  
});  
  
con.connect(function(err) {  
  if (err) throw err;  
  console.log("Connected!");  
});  
~  
~
```

Make sure to `:wq` then we will use the command `node yourfile.js`

```
[ec2-user@ip-10-123-21-191 ~]$ node mysql_connection.js  
Connected!
```

Exit out of the instances. We are done here.

Make sure to run a `terraform destroy` to avoid incurring extra charges for your resources. Thank you for reading!
